Abstract

Objective: 1) To examine the efficacy of segmentary relaxation (EMG Biofeedback + Stimulation) compared to conventional occupational Therapy in the Functional Recovery of Hemiplegics hand.

2) To study in which stage of Brunnstrom , segmentary relaxation shows most significant results.

Setting: The study was conducted in the Dept of Occupational Therapy, N.I.O.H, Kolkata.

Design: Experimental group underwent 20 sessions (5 days a week) of Segmentary Relaxation along with Conventional Therapy whereas control group underwent only conventional therapy for the same no of sessions.

Assessments: Upper limb disability was assessed with Action Research Arm Test. Brunnstrom Stage and Goniometric measurement of wrist extension was also recorded.

Results: There was an improvement in the joint range of motion of wrist extension, 2% in control group and 40% in the experimental group. Within group results in the experimental group showed 13.6% improvement in stage 2 to 3 ,14.6% in stage 3to 4 and 40% in stage 4 to 5. The results for ARAT were not significant $p=0.24$. Chi square test showed significant results for the treatment effect at $p = .02$.

Results

There was an improvement in the joint range of motion of wrist extension, 2% in control group and 40% in the experimental group. Within group results in the experimental group showed 13.6% improvement in stage 2 to 3 ,14.6% in stage 3to 4 and 40% in stage 4 to 5. The results for ARAT were not significant $p=0.24$. Chi square test showed significant results for the treatment effect at $p = .02$.

INTRODUCTION:

Rehabilitation of the upper extremity in patients who have sustained a stroke poses a major challenge to therapists. In a review of studies on upper extremity recovery , Gowland stated that only 4% to 9% of patients regained normal function , 23% to 43% regained some useful function and 16% to 28% did not have return of any voluntary movement in upper limb1 .Different treatment strategies for the rehabilitation of hemiplegics patients are available today , such as conventional exercise programs ,PNF, muscle strengthening and physical conditioning programs , neurophysiologic approaches and functional electrical stimulation .Most of these studies have reported that EMG

biofeedback can help to achieve improvements even in the chronic state2 .

Feedback is an engineering term defined as a method of controlling a system by re-inserting into it the results of past performance .Among the most expressive therapeutic advances, those relating to spasticity control need to be acknowledge43 . Dimitrijevic and Soroker 1994 studied electrical stimulation effects through a wire-mesh glove on upper extremities of hemiplegics patient's .The preliminary results indicated beneficial effects such as decrease in muscle hypertonia and facilitation of hand-isolated movements.

Upper extremity hemi paresis is a prominent impairment following stroke and has a significant impact on activities of daily living and quality of life .recovery of upper extremity function is most rapid during the first months after stroke .However, even 3 months after stroke only 20% of stroke survivors have normal upper extremity

function. Accordingly, the majority of stroke survivors report that impaired upper extremity function is a major problem and this is associated with low level of subjective well being⁴. The loss of function in the limb of stroke survivors is the result of lack of inhibition from the higher centers. Some studies (Alfieri,1985;Kraft et al,1995) analyzing FES denoted relief of spasticity and opening of the hemiplegics hand , believing that this fact is due to the mechanism of reciprocal inhibition of the fingers flexion muscles, at the moment when the extensor muscles in hemiplegics patients are stimulated⁵.

There is growing evidence that electrical stimulation has a positive effect on upper extremity motor recovery following stroke. Therefore electrical stimulation might be an adjunct in the rehabilitation of patients with stroke⁴. Emg -biofeedback is not a system of treatment in itself, but a technique that can be incorporated into many treatment programmes.

Biofeedback is a specialized form of feedback that provides information directly to a patient about internal biological mechanisms via a sophisticated electronic device. To quote John Basmanjian (the " Father" of EMG Biofeedback), biofeedback is the technique of using equipment (usually electronic) to reveal to human beings some of their internal physiological events ,normal and abnormal, in the form of visual auditory signal in order to teach them to manipulate these otherwise involuntary or unfelt events by manipulating the displayed signals⁶.

Feedback may facilitate plastic changes within the central nervous system. Mechanisms that might be invoked include one or more of the following elimination of active inhibitory influences, unmasking of existing pathways to sub serve functions, development of new movement strategies , transfer of function to intact neural structures , use of alternative pathways or sprouting of collateral axons to form new synapses⁷.

Electrical stimulation provides effective joint positioning by eliciting activity from weakened or inactive muscle groups. Electrical stimulation has the potential to strengthen these muscles when volitional activation is present.

Electrical stimulation may facilitate

neuromuscular re-education as well, the stimulation provides added afferent information to the central nervous system with attention to task and attempts to volitional activation, this afferent input may contribute to neuromuscular re-education of stimulated area⁸. When the afferent nerve is stimulated, the A alpha fibers are reflex stimulated and as a result the muscle contracts. Initiation of voluntary contraction takes place through primary activation of the small motor neurons to set up a stretch reflex and bring about activation of the alpha neurons⁹.

Relatively little attention has been paid to the potential of effect of EMG Biofeedback + Stimulation in the functional recovery of hemiplegics hand Hence this study was carried out to see the effectiveness of EMG Biofeedback +Stimulation for the functional recovery of hemiplegics hand.

Purpose

The purpose of this study was to determine whether there is conclusive evidence regarding the use of EMG Biofeedback + stimulation for improvement in upper extremity function in stroke patients.

Hypothesis

There will be Functional recovery of hemiplegic hand and an increase in the joint range of motion for wrist extension after the application of EMG Biofeedback +Stimulation.

Nullhypothesis:

There will not be any increase in the functional recovery of hemiplegic hand and an increase in the joint range of motion of wrist extension after the application of EMG Biofeedback +Stimulation.

Inclusion criteria

- 1) Inability to perform voluntary motion in the upper extremity following stroke & significant room for improvement in one muscle group.
- 2) Relatively uncomplicated history.
- 3) Workable amount of cooperation and attention.
- 4) No significant visual and auditory deficits.
- 5) Significant motivation.

Exclusive criteria

- 1) Flank hemiplegia.
- 2) Dementia.
- 3) Deformity of upper limb.
- 4) Any incidence of receptive aphasia.
- 5) Any cardiac problem.

Methodology design

The design is a different subject experimental design.

Setting

The study was conducted in the Occupational Therapy Department of N.I.O.H., Kolkata.

Subjects

A total of 30 subjects with mean age group of 57yrs participated in the study. Subjects were included in the study only after taking individual consent.

Instruments/cales used

- 1) Biofeedback Instrument
- 2) Action Research Arm test
- 3) Goniometer
- 5) Brunnstrom stage of motor recovery

Assessments:

Basic information of all the patients was taken (demographic data, history, motor evaluation, evaluation of hand function, functional evaluation and ADL evaluation was recorded), for referral. Specific assessments required for the study were Brunnstrom stages of hand recovery, Goniometric measurement for active selective range of motion of wrist, and action research arm test. Subjects were also assessed for the ability to follow simple instructions by administering a part of mini mental status examination.

Experimental group

Experimental group received EMG Biofeedback +Stimulation for wrist extensors and finger extensors. Subjects were also provided with the conventional Occupational therapy.

Control group

Control group received only the conventional Occupational Therapy for 20 sessions.

Procedure

Duration of Treatment

Total of 30 minutes session, 15 minutes each for wrist extensors and finger extensors with a in between phase suitable to the patients compliance to the the program. control group underwent the conventional therapy for one hour each day for 20 sessions.

Treatment

Relaxation

1) Relaxed position is determined, the patient is asked to maintain the reduced EMG activity as he performs various motions with opposite extremity.

2) Conversations with the patient may be used by therapist as a measure of the patient's ability to maintain the relaxed state while his attention is diverted.

3) Patient is asked to maintain a relaxed state during a full passive stretch of the involved muscle.

Position:

Shoulder flexion-10* to 15*

Abduction-20* to 25*

Elbow flexion-10* to 15*

Wrist flexion - l (Maximum)

Finger flexion - Maximum 10

Electrode application:

Select the muscle to be monitored.

Prepare the skin site by cleaning with spirit for application of electrodes over the muscle bellies of wrist extensors and for the muscle belly for finger extensors.

Electrodes spacing is 3.5 cm to 5 cm.

Arc of motion

The wrist extensors and finger extensors were monitored only after relaxation of flexors of the wrist and the fingers .If too much flexor activity was evident, subjects were targeted for smaller arc of motion with success in smaller range of motion, larger arc of motion was aimed.

Parameters

The parameters used for each patient were adjusted to produce the most harmonious

movement possible .Width of pulse varied between 100 micro se to 200 micro sec and the frequency varied between 40 hertz to 50 hertz. A long ramp on time is used to avoid activating of stretch reflex in a spastic antagonist.

During the biofeedback session which was in the protocol the patient was asked to contract the wrist extensors and the finger extensors voluntarily

Results

The data was analyzed by spss software. The results indicated an improvement in the joint range of motion of wrist extension, the control group achieved 2% improvement in range in

experimental group 25% improvement was seen Not much difference was observed on the affect on improvements in joint range of motion by the stage of recovery. The results are tabulated in Table, Chi suare test was doneto see the effect of the stimulation and conventional therapy.The result was significant at $p < .001$ (Table-3). .As there was minimum effect on both stages 2 to 3 and 3 to 4 and moderate effect on stages 4 to 5.The nominal values moderate and minimum effect.Titration between three groups were done.The results showed sinificant results for stage 4 to 5 at $p < .02$ and for stages 3to 4 and 2 to 3 the results were insignificant

Table 1

DEMOGRAPHIC AND CLINICAL FEATURES PF SUBJECTS		
	EXPERIMENTAL GROUP(n=15)	CONTROL GROUP (n=15)
Age/yr	57 ± 10.53	57 ± 11.27
Male /Female	13/2	10/5
Duration of stroke (months)	36/09	36/4
Stroke type,inf/hem	7/7	6/7
Side of hemi paresis(R/L)	9/5	9/4

TABLE:2 CORRELATION OF STAGE OF RECOVERY AND WE JROM

N	BRUNNSTORM STAGE OF RECOVERY	% OF IMPROVEMENT IN JROM OF WRIST EXTENSION
30	2-3	13.6%
	3-4	14.6%
	4-5	40%

Table 3 : Effect of treatment marginal

Group - 1(experimental)	A 15	B 0	A+B 15
Group 2(conventional)	C 7	D 8	C+ D 15
	A+C=23	B+D=7	Grand =30
Chi square test was done	=5.300, P value = .001		

There remained a tendency for total ARAT score to be improved in the experimental group; however this difference was not statistically significant between the two groups.

P=0.24.

Discussion

The hypothesis that there will be an improvement in the functional recovery of upper extremity in the stroke patients was not justified as the results were not significant at $p=0.24$. Studies by Lourecao et al leads to conclude that use of FES on upper extremity should be at least for 6 months, when applied twice a week. Probably the duration of treatment was not long enough; this may justify the insignificance in the recovery of upper extremity function. There was an improvement in the joint range of motion of wrist extension in both the groups but the experimental group cited better results. Feedback may facilitate plastic changes within the CNS⁷. Basmanjian et al in his study states that studies on new therapy for upper limb function in stroke patients should be done at the ideal stage when the surviving brain tissue has its greatest plasticity i.e. up to 4 months post stroke in patients who show greatest promise. And as most patients in the study did not belong to the acute stage it may be suggested that this may be one of the reasons for the insignificance in the results¹¹.

. There was not much difference in the wrist extension range of motion in between the stage group 2 to 3 and 3 to 4. This is supported by Armagaon et al, 2003, who in their study revealed similar results. This may be because electrical stimulation has combination of effects including those at the level of muscle and also a central effect associated with improved motor relearning. However the subjects in stage 4 to 5 achieved 40% improvement². Kroon 2005 states although there not direct evidence electrical stimulation

provokes motor activation and is associated with cutaneous , muscle and joint proprioception feedback .It may be that patients belonging to stage 4 to 5 get more muscle and joint proprioception feedback which adds to the better improvements in joint range of motion. Chi square test show significant results for the relation between the dependant and independent variable. P value $< .001$ Wolf 1983 examined the effect of EMG Biofeedback treatment protocol on qualified changes in neuromuscular measures and functional activities among the treatment of 22 cases chronic stroke patients. Its results concluded that EMG Biofeedback can be beneficial in restoring improved upper extremity function among chronic stroke patients⁶. Significant results of the expected improvement is supported by the above study by Wolf .The stimulation effects also showed significant results at $p< .001$,this is supported by previous study by Wolf 1983.

Conclusion

The study provides conclusive evidence regarding the use of EMG Biofeedback + stimulation for improvement in upper extremity function in stroke patients .The study did not show statistically significant results for ARAT, therefore it may be that the estimated size was small, hence future studies are recommended with a larger sample size. Studies may be conducted to see whether lesion site has any correlation to improvement in upper extremity function and joint range of motion for wrist extension as a result of the therapy.

Acknowledgement

I would like to take this opportunity to thank Dr..Ratnesh Kumar (Director, N.I.O.H), to conduct the study in the institute. I would also like to thank all my friends the staff members. Special thanks to all the subjects Last but not the

least I would like to thank my parents and sisters for their immense support throughout the period.
